# Determination of Dynamic Tensile Strength of Concrete Using a Split Hopkinson Pressure Bar

Nik Benko, John Callaway, Nick Dorsett, Martin Raming
ME EN 6960
May 1, 2018

#### Concrete Failure

- Concrete is a common building material bridges, buildings, roadways, etc.
- Concrete is strong in compression and weak in tension.
- Failure of concrete structures is often the result of tensile failure.
- Failure of concrete is dependent on the loading rate. [1]
- Design of structure needs to account for loading rate.

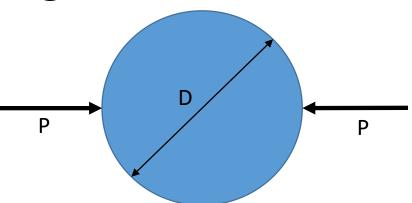

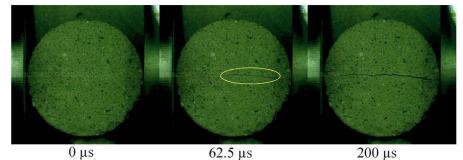

## Tensile Testing of Concrete

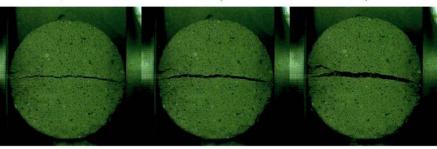

$$\sigma_t = \frac{2P}{\pi Dt}$$

t = thickness of specimen

Brazil Disc Specimen (ASTM D 3967-08):

 $800 \mu s$ 

- Compression creates a tensile failure of the specimen.
- Test can be performed quasistatically or dynamically at high strain rates.

 $400 \mu s$ 

 $2000 \mu s$ 

<sup>\*</sup> High speed imagery of concrete Brazil Disc tes from X. Jin et al [1]

# Split Hopkinson Pressure Bar (SHPB)

- In 1914, Hopkinson introduced a technique for measuring dynamic material strength [4]
  - Cylindrical steel bar with pellet lightly attached to end
  - Response of bar determined by measuring momentum of pellet
- In 1948, Davies did a critical review of this experimental technique [5]
  - Microphone and oscillograph used to make photographic record
  - Dispersion correction equations derived
- Kolsky further adapted Davies' method in 1949 by introducing a second bar on the other end of the specimen with a second microphone at the end
  - Record made of both incident and transmitted pulses [2]

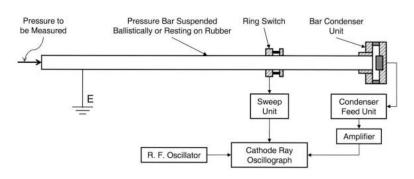

Fig. 2 General arrangement of the apparatus developed by Davies. Reproduced from Fig. 1, Davies [5], p 382.

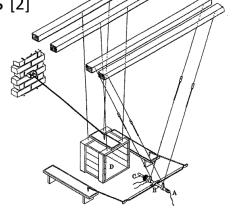

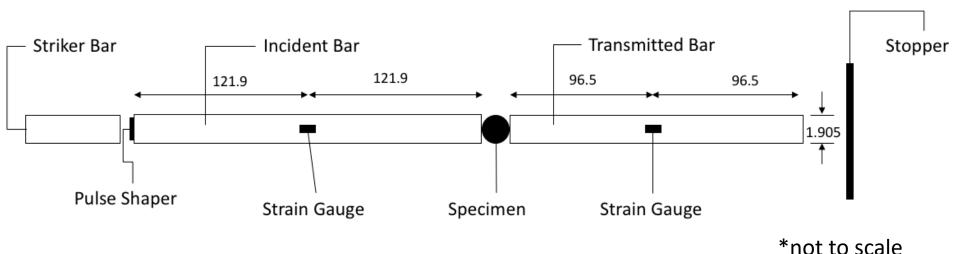

Fig. 1 Apparatus developed by Bertram Hopkinson for the measurement of pressure produced by the detonation of gun cotton. [3] Reproduced from Fig. 12, Hopkinson [4], p 451.

#### Bar Setup

- Utilizes thin bars to propagate stress wave into sample
  - Thin bars simplify motion into one dimension
  - Bars must be homogenous and have a uniform cross section
  - The impact from the striker bar must not exceed elastic limit of bars
- Strain caused by stress wave is measured at the midpoint of each bar.
  - Full Wheatsone bridge configuration used to isolate axial strain
- Dispersion effects present from finite bars

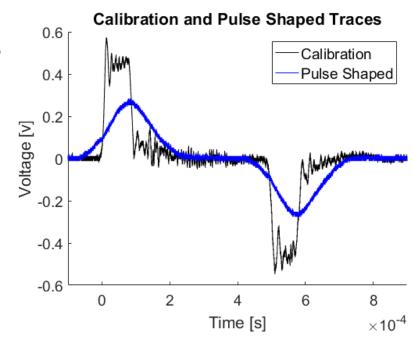

## **High Frequency Compensation**

#### **Pulse Shaping**

- Addition of a material between the incident and striker bar – lead, plastic, paper, etc.
- Creates a mechanical filter that reduces frequency content of the impulse wave(s).
- Pulse shaper material depends on SHPB and specimen materials
- Pulse shaped signal should mimic material response of specimen [6]

#### **Dispersion Correction**

Utilize non-linear curve fitting and Fourier series to correct for dispersion
 [7]

$$F(n\Delta T) = \frac{A_0}{2} + \sum_{k=1,2,\dots}^{N} \left[ A_k \cos(k\omega_0 n\Delta T - \phi_{TS}) + B_k \sin(k\omega_0 n\Delta T - \phi_{TS}) \right]$$
[3]

#### Wave Position Alignment

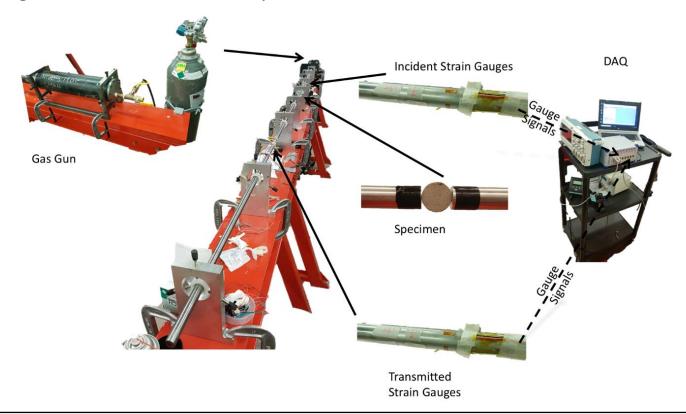

- Since strain gauges are positioned in the middle of the incident and transmitted bars, waves must be aligned forward/backwards in time.
- Utilizing the bar wave speed and known position of strain gauges waves are aligned in time.
- Force equilibrium can then be determined by converting voltages to strain.

$$F_1 = A_{Bar} E_{Bar}(\varepsilon_I + \varepsilon_R)$$
 
$$F_2 = A_{Bar} E_{Bar}(\varepsilon_T)$$

#### **Test Procedures**

- Gas gun was utilized to propel striker bar, pressure was varied from 8 to 12.5 psi.
- Concrete Brazil Disc specimens were 19.05 mm in diameter and 6.35 mm thick.
- SHPB were made of 7075-T6 aluminum.
- Lead pulse shaper was 9.525 mm in diameter and 1.058 mm thick.
- Sampling was at 125 MHz with a period of 1ms.

# Dynamic Tensile Strength

Dynamic Tensile Strength:

Mean: 15.77 MPa; Median: 15.18 MPa Standard Deviation: 3.60 MPa

Quasi-Static Tensile Strength: 2.2-4.4 MPa [8]

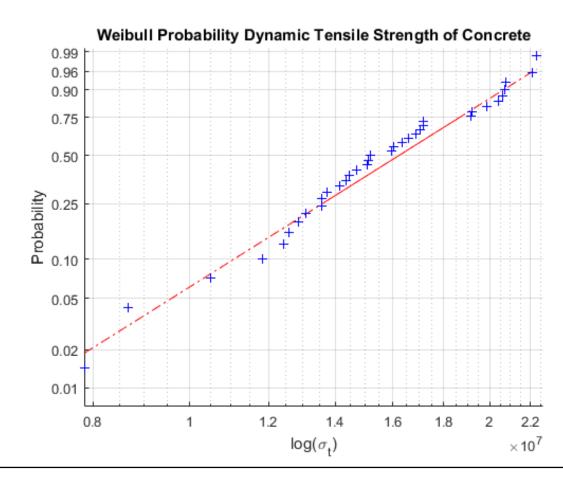

Weibull Analysis [9]:

$$p(x) = 1 - e^{-\left[\frac{(x-x_o)}{b}\right]^m}$$

Where:

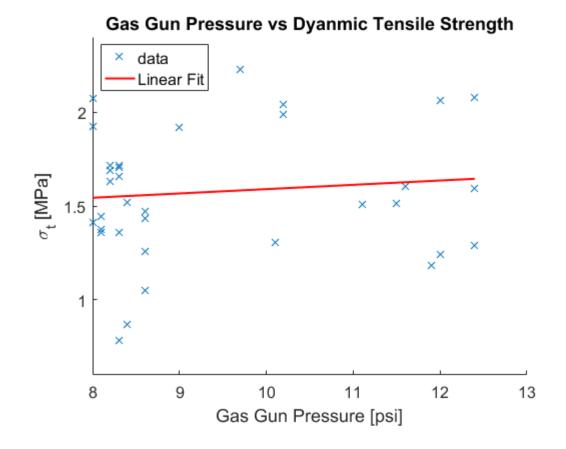

$$x_o = 7.84 \text{ MPa}$$
  
b = 17.18 MPa  
m = 4.9951

N = 35 specimens

## Gas Gun Pressure and Tensile Strength

- Gas Gun Pressure and Strain Rate were expected to be correlated.
- No correlation was seen when looking at cumulative class data.
- Pulse shaping between groups could impact correlation.

#### Conclusions

- A positive correlation between strain rate and ultimate tensile strength was confirmed.
- Minimal to no correlation between gas gun pressure and strain rate.
- Weibull statistical analysis showed moderate variance of strength values.
- Further investigation of strain rate using a measured striker bar velocity would allow the relationship between strain rate and tensile strength to be better quantified.
